Send me your database (a dump)

For Michael · from Mithun · about 10 minutes

Why

The repo has your code, but not your data. The data lives inside your own PostgreSQL on your PC. A **dump** is a snapshot of that database saved as one file. I will restore it on my computer, so my ESP32 scanner can talk to your Django app and use your real boxes, tags and orders. Please follow the steps below on your Windows PC.

Step 1: Find your database name and user

Open your **.env** file in `Web_Application` and look at `DB_NAME` and `DB_USER`. (Your setup doc uses `factory`, your screenshot showed `precapstone`. Use whichever your app really uses.)

> **Do not send me the .env file or your DB password.** I only need the names, and I will make my own password.

Step 2: Check that pg_dump works

Open PowerShell and run:

```
pg_dump --version
```

Write down the version number it prints (for example 16.4). I use PostgreSQL 18, so tell me if yours is newer than 18. If PowerShell says the command is not found, use the full path instead, for example:

```
& "C:\Program Files\PostgreSQL\16\bin\pg_dump.exe" --version
```

Step 3: Make the dump

Stop your Django server first (Ctrl+C), so nothing changes while you copy. Then run this, replacing the two names with the ones from Step 1:

```
pg_dump -U YOUR_DB_USER -h localhost -Fc -f factory.dump YOUR_DB_NAME
```

It asks for your database password. Type it (nothing shows on screen) and press Enter. If your Postgres is not on the default port, add `-p PORT`. `-Fc` makes the compact format that `pg_restore` needs, so please keep it.

Step 4: Check the file

A file called `factory.dump` should now exist in the folder where you ran the command. Check that it is not empty (usually at least a few hundred KB):

```
dir factory.dump
```

If it is 0 KB or the command printed an error, send me the error text and I will help.

Step 5: Send it to me privately

Send `factory.dump` to me by Discord direct message, or a private shared drive link. **Do not commit it to GitHub.** It is ignored by git on purpose, because it contains your users' password hashes and all your order data.

Step 6: Two more things I need

1. Uploaded files. Drawings that people upload are stored as files on disk, not inside the database, so the dump does not include them. If you have a folder for uploads (look for a `media` folder in Web_Application), zip it and send it too. If you have none, just tell me.

2. Latest code pushed. Please commit and push all your latest code and migration files, so my copy of the app matches your database. Tell me the last commit you pushed. Also tell me one admin username I can log in with, or I will make my own with `createsuperuser`.

What I will do next (so you know)

1	Create an empty database on my PC
2	Restore your dump into it with pg_restore
3	Point my .env at it and run migrate
4	Create a scanner device in admin and copy its API key
5	Change my ESP32 to POST to /api/scan/ with the X-API-Key header

Checklist

[ ] I know my DB name and user
[ ] I wrote down the pg_dump version
[ ] factory.dump exists and is not empty
[ ] I sent it privately (not on GitHub)
[ ] I sent the uploads folder or said there is none
[ ] My latest code is pushed and I told Mithun the commit
